Executive Summary

ChatGPT Enterprise is OpenAI's commercial offering built for organizational deployments. Three things set it apart from the consumer and Teams-tier products: the data handling commitments it makes, the administrative controls it puts in the hands of IT teams, and the session context capacity it provides. Underneath all of that, the model is essentially the same. What differs is how access is governed and what protections surround it.

For organizations evaluating enterprise conversational tools, ChatGPT Enterprise is a serious option. Brand recognition helps with adoption—people already know the product, which removes much of the internal education work. The security posture addresses the most common legal objections, and the admin tooling covers what most mid-to-large organizations actually need. That said, it is not the right answer for every situation. Companies in heavily regulated sectors, those with strict data residency requirements, or those needing deep integration with proprietary internal systems may find purpose-built alternatives fit better.

This report works through ChatGPT Enterprise across five dimensions: core capabilities, security architecture, administrative controls, workflow integration, and competitive positioning. The intended audience is procurement teams, IT decision-makers, product managers, and strategy professionals who need a grounded assessment rather than a vendor-produced overview.

What ChatGPT Enterprise Actually Is

Before evaluating what ChatGPT Enterprise does, it is worth being clear about what it is not. It is not a purpose-built enterprise platform in the tradition of Salesforce, Workday, or ServiceNow. There are no industry-specific workflows

baked in, no pre-built connectors to vertical data sources, and no professional services arm ready to configure it against your specific processes. What it is, more precisely, is a governed access layer to a highly capable general-purpose model with the security controls, audit capabilities, and administrative features that enterprise IT and legal teams need before they will approve anything at scale.

OpenAI launched the product in August 2023, targeting organizations already using the consumer or Teams tiers but needing formal data protection guarantees, user management, and organizational oversight. Since then the product has added custom instructions, expanded context windows, and API integration options. OpenAI's own documentation describes it as providing enterprise-grade security and privacy, GPT-4 access with a larger context window, advanced data analysis, and admin controls for workspace management — a description that is accurate, if worth unpacking.

The security commitment rests on one guarantee that matters most in practice: OpenAI does not use data submitted through ChatGPT Enterprise to train its models by default. That is the sentence enterprise legal teams need to see. It is a contractual distinction from the consumer product, and it addresses the concern that comes up in almost every organizational evaluation.

The 128,000-token context window is a genuine capability difference. At roughly 90,000 to 100,000 words of capacity per session, the product can take in most business documents, contracts, and research papers without chunking them. For organizations whose work involves reviewing lengthy materials, this matters considerably more than the headline number suggests.

Core Capabilities

ChatGPT Enterprise covers the broad territory of knowledge work: writing, analysis, summarization, research synthesis, code review, structured data interpretation. The table below maps the main capability areas to their most common organizational uses, alongside a direct assessment of where the product earns its keep and where it starts to show its edges.

Capability Area	Common Use Cases	Performance Assessment	Practical Ceiling
Long-form document analysis	Contract review, policy comparison, report synthesis	Strong for extraction and summarization tasks	Cannot verify facts against external sources in real time
Code generation and review	Writing boilerplate, debugging, documentation, code explanation	Strong across mainstream languages; weaker on proprietary frameworks	Should not replace senior code review in production contexts
Structured data interpretation	CSV analysis, financial table reading, survey results	Reliable for pattern identification and basic calculation	Not a substitute for dedicated BI tooling at scale
Writing and editing	Draft creation, tone adjustment, professional correspondence	Consistently strong across most business writing contexts	Output needs human review; brand voice requires explicit instruction
Research synthesis	Pulling together information across multiple documents	Strong when documents are provided in context	Has no live internet access in standard Enterprise sessions
Custom GPTs	Automating recurring workflows, internal knowledge bases	Practical for well-defined, repetitive tasks	Requires ongoing maintenance as organizational context evolves

Two observations worth pulling out of that table. The code generation capability tends to get underestimated by non-technical evaluators and overestimated by technical ones. For routine work test case generation, SQL queries, documentation, data reformatting it saves real time. For complex architectural decisions or anything touching production systems, treat it as a starting point for discussion, not a conclusion. It has no knowledge of your codebase, your team's conventions, or the decisions that shaped your system's history.

The custom GPT functionality is the second thing worth highlighting. Organizations can build configured assistants on top of the base model with specific instructions, behavioral guardrails, and in some cases live data connections. For recurring use cases like HR policy Q&A, procurement guidance, or new hire onboarding, a well-built custom GPT makes a real operational difference. The honest caveat: these configurations age. Instructions that were accurate in January become misleading by June if internal policies have changed and nobody has updated the tool.

Security and Data Architecture

Security architecture is where most enterprise evaluations get decided. The questions are predictable: does the vendor use our data to improve their product, where exactly is our data processed and stored, and what audit and access controls do we actually control? ChatGPT Enterprise has credible answers to the first and third. The second is more nuanced.

Training data: the enterprise terms are explicit that data submitted through ChatGPT Enterprise is not used for model training by default. Most enterprise legal and privacy teams have found this sufficient. On processing and storage, the answer takes more care. OpenAI runs its infrastructure on Microsoft Azure. For organizations operating under strict data residency requirements in specific jurisdictions, this needs direct legal review the fact that Azure has regional infrastructure does not automatically satisfy every sovereign data requirement.

Encryption in transit and at rest is table stakes for any enterprise SaaS product. It is confirmed here. The more operationally relevant conversation for most IT teams is about access controls and audit logging, where the product has more to say.

Security Feature	What It Provides	Enterprise Relevance
No training on Enterprise data	Contractual commitment that submitted data is not used for model improvement	High — addresses the primary legal objection to deployment
Encryption in transit and at rest	TLS 1.2+ in transit; AES-256 at rest	Standard — expected and confirmed
SSO integration	SAML-based single sign-on with major identity providers	High — required for most enterprise IT environments
Domain verification	Restricts enrollment to verified organizational email domains	Medium — useful for managed deployments
Audit logs	Conversation-level activity logging accessible to admins	High — required for compliance and incident response
Usage analytics	Aggregate usage data by team and user	Medium — useful for ROI measurement and adoption tracking
Data retention controls	Configurable conversation retention policies	Medium-High — relevant for regulated industries

The gap worth naming: geographic data residency guarantees are thinner here than with vendors operating dedicated regional cloud environments. A multinational subject to EU data sovereignty requirements, or regulated by a financial authority with specific data location rules, should get legal review before assuming Azure's regional footprint covers the requirement. The SOC 2 Type II report exists and is available under NDA if your procurement process requires it, request it at the start of the evaluation, not the end.

Administrative Controls and Deployment

The admin layer is where the product most visibly separates itself from the consumer and Teams tiers. IT and operations teams will find controls that satisfy the practical management needs of most organizations. It is not the full governance stack that a specialized enterprise platform provides, but for the majority of deployments it is enough.

The admin console handles centralized user management inviting, managing, and removing users, and controlling which features are available to which groups. SSO via SAML is supported, which is a practical prerequisite for any IT environment managing identity through Okta, Azure AD, or similar. Workspace-level usage reporting gives operations teams a picture of adoption across the organization.

Where the controls get thinner: granular role-based access. Organizations needing fine-grained permissions — restricting employee groups to specific GPT configurations, gating features by department or clearance level — will find less flexibility than they might expect. The product gives broad control over workspace access and feature availability, but attribute-based access control at the level that mature identity platforms support is not there yet.

Custom GPT deployment within the workspace is worth examining carefully. Administrators can publish custom GPTs organization-wide, which is genuinely useful for standardizing usage and embedding institutional knowledge into the tool. The governance consideration: users with appropriate permissions can also build and share their own custom GPTs within the workspace. Without a review process before broader rollout, this creates scope for inconsistent or outdated configurations to spread alongside the sanctioned ones.

Workflow Integration

Integration quality is often what determines whether a tool becomes part of how an organization works or drifts into occasional personal use. For ChatGPT Enterprise, the answer depends heavily on which integrations matter most and there is a wide range of feasibility depending on the use case.

External integration runs through the Custom GPT Actions framework, which lets configured assistants make API calls to outside services. Done well, this enables genuinely useful connections querying an internal knowledge base, pulling live CRM data, triggering internal workflow requests. Done poorly, it creates a maintenance overhead that erodes quickly. The important thing to understand is that this requires development work to build and ongoing attention to sustain. It is not a connector library that an administrator can configure in an afternoon.

Organizations already invested in Microsoft's ecosystem face a specific evaluation question. Microsoft 365 Copilot runs on the same underlying model technology but sits much more natively inside Word, Excel, SharePoint, and Teams. For organizations where daily work happens primarily in those tools, the integration story is more coherent there than here. The choice between the two or the decision to run both deserves deliberate analysis rather than a default in either direction.

The table below maps common enterprise workflow scenarios to their realistic integration feasibility:

Workflow Scenario	Integration Feasibility	What Is Required	Alternative to Consider
Internal document Q&A (policy, HR, procurement)	High — achievable with custom GPT + file upload	Custom GPT configuration; document management process	Microsoft 365 Copilot if SharePoint-native
CRM data enrichment or summarization	Medium — requires API action setup	Developer resource; API access from CRM vendor	Salesforce Einstein, HubSpot AI tools
Code review and documentation generation	High — core capability, low integration overhead	Organizational conventions in system prompt	GitHub Copilot for IDE-native experience
Customer support draft generation	Medium — requires human review workflow	Process design; escalation protocol	Zendesk AI, Intercom Fin for native ticketing integration
Financial reporting synthesis	Medium — works well with document upload	Strong data governance process; output review protocol	Dedicated BI tools for structured data at scale
Legal contract review	Medium — useful for preliminary analysis	Legal team review of all outputs; risk protocol	Harvey AI or Ironclad for purpose-built legal workflows

Where ChatGPT Enterprise Performs Well

Being specific about where the product earns its place matters more than a general endorsement. The strongest case for ChatGPT Enterprise is in knowledge work that currently takes up disproportionate time from skilled people without actually requiring their most valuable judgment.

First drafts are the clearest illustration. At a professional services firm where consultants spend several hours drafting client-facing documents, the time investment drops substantially when a well-configured tool produces a structurally sound draft in minutes. The professional still reviews, edits, and owns the output that part does not go away. What changes is the nature of the work: refinement rather than creation from a blank page. For most knowledge workers, that shift is meaningful.

Document analysis at scale is the second standout. Organizations handling large volumes of contracts, regulatory filings, technical specifications, or research reports can use the extended context window to extract specific information, compare provisions across documents, or produce structured summaries without the time investment of manual reading. Law firms, financial institutions, and consulting organizations in this position have reported genuine efficiency gains, though most have been measured about citing specific figures publicly.

Internal knowledge access is the third case worth naming. Organizations that configure a custom GPT with accurate, current information about internal processes, systems, and policies give new employees a self-serve resource for the routine questions that otherwise land on experienced colleagues. The configuration requires discipline to keep current, but the return is visible particularly in organizations with significant hiring volume or complex internal processes that take time to learn.

Limitations and Known Constraints

A credible evaluation has to be direct about what the product does not do well. Several limitations are significant enough to shape deployment decisions and use case boundaries.

Factual Reliability

The model can produce confident, fluent, and factually wrong responses. This is not a defect specific to this product it is a characteristic of the technology type that every product in the category shares to some degree. In enterprise workflows where the accuracy of specific claims matters regulatory guidance, financial figures, legal precedent every output needs review by someone with enough domain knowledge to catch errors. Treat it as a capable research assistant, not a reference source.

No Real-Time Information Access

Standard sessions have no live internet access. The model's knowledge has a training cutoff, and without a custom GPT configured with browsing or connected to an external data source, current information is not available. For use cases where recency matters market developments, regulatory changes, competitor moves this is a real constraint that needs to be addressed in the configuration or the workflow, not assumed away.

Pricing Transparency

Pricing is not publicly listed. Organizations engage OpenAI's sales team for a quote, and the contract is typically structured as an annual commitment with per-seat pricing that varies by volume. Third-party reporting has suggested figures in the \$30–\$60 per seat per month range, but those should not be treated as authoritative. The opacity makes direct comparison with competitors who publish pricing genuinely harder, and smaller organizations may find the minimum commitment requirements a barrier before they even get to a meaningful evaluation.

Integration Depth

Connecting the product to existing organizational systems requires development work, as the workflow section makes clear. Organizations without in-house technical resources to build and sustain API integrations will find the integration story less compelling than the capabilities summary suggests. This is true of enterprise software broadly, but it is worth stating plainly in procurement discussions rather than discovering after the contract is signed.

Context Window Limitations in Practice

The 128,000-token context window is large, but performance across very long documents is not uniform throughout. Research has shown that models tend to handle information near the beginning and end of a long context more reliably than material buried in the middle sometimes called the lost-in-the-middle effect. For organizations whose core use cases involve very long documents, this deserves real testing on representative samples before drawing broad conclusions about capability.

Competitive Landscape

The market for enterprise conversational tooling has expanded considerably. Making a good decision about ChatGPT Enterprise requires understanding what the alternatives actually offer and the conditions under which they fit better.

Product	Primary Strength	Best Fit	Key Consideration vs ChatGPT Enterprise
Microsoft 365 Copilot	Deep integration with Office suite and Microsoft ecosystem	Organizations standardized on Microsoft 365	More coherent for Word/Excel/Teams workflows; requires M365 E3/E5 license
Google Workspace Duet AI	Native integration with Google Docs, Gmail, Sheets, Meet	Google Workspace-first organizations	Stronger for real-time collaboration; weaker outside Google ecosystem
Amazon Q for Business	AWS-native; strong for cloud operations and developer workflows	AWS-heavy technical teams	More technical in focus; less suited for general knowledge work
Anthropic Claude for Enterprise	Strong reasoning, very long context, careful safety design	Use cases requiring nuanced analysis or sensitive content handling	Less brand recognition but strong capability ceiling; also no public pricing
Harvey AI	Purpose-built for legal workflows; trained on legal content	Law firms and in-house legal teams	Specialized advantage over ChatGPT Enterprise for pure legal use cases
Glean	Enterprise search and knowledge retrieval across existing systems	Organizations with fragmented internal knowledge bases	Complementary rather than competitive; different primary use case

The most important observation about this landscape: for most organizations, the real decision is between ChatGPT Enterprise and Microsoft 365 Copilot. The product quality difference is less significant than the question of where work actually happens. Organizations whose employees live in Word, Excel, and Teams will get more value from Copilot's native integration. Organizations where work is fragmented across tools or where the primary use cases are research and document analysis rather than document creation often find the calculus goes the other way.

Running both products is a real option, and some organizations do. ChatGPT Enterprise for general research and analysis, Copilot for Office-native workflows. The overhead is real two vendor relationships, two training programmes, two governance frameworks to maintain but for organizations where the use cases genuinely differ, the approach makes sense.

Decision Framework: When to Choose ChatGPT Enterprise

The table below is a working framework for structuring the evaluation, not a scoring system that produces an automatic answer. What it does is surface the questions that most consistently determine whether ChatGPT Enterprise is the right fit for a given organization.

Evaluation Dimension	ChatGPT Enterprise is a Strong Fit When...	Consider Alternatives When...
Primary workflows	Work is cross-tool and general in nature research, writing, analysis	Work is deeply embedded in a specific platform (Office, Google, Salesforce)
Technical resources	Organization has developers able to build and maintain custom configurations	No in-house technical resource to build integrations; needs turnkey solution
Regulatory environment	Standard enterprise security controls satisfy compliance requirements	Strict data residency laws require guaranteed geographic data isolation
Use case specificity	General knowledge work productivity is the primary goal	Use case is domain-specific (legal, clinical, financial analytics)
Microsoft ecosystem	Organization uses a mix of tools or is not standardized on M365	Organization is fully standardized on Microsoft 365 with E3/E5 licenses
Brand and adoption	Brand familiarity helps drive internal adoption without extensive change management	Internal adoption is not a concern; technical capability is the only evaluation criterion

One dimension the table does not capture: organizational maturity around responsible use. The product provides the technical capability. The operational processes required to use it safely are the organization's work to do. Companies that deploy without clear guidance on what the tool should and should not be used for, how outputs get reviewed before use, what categories of information should not be submitted will run into problems regardless of how well the technology performs. The vendor does not solve that problem. The organization does.

Implementation Considerations

Most enterprise software evaluations spend too little time on what happens after the contract is signed. For ChatGPT Enterprise, the implementation phase breaks into four workstreams that each need explicit organizational ownership.

Technical Setup and Security Configuration

SSO integration, domain verification, and audit log configuration are the baseline technical tasks. None of these are typically complex for a competent IT team, but they do require coordination between IT, security, and the OpenAI account team. Building custom GPTs for priority use cases follows, and that part is iterative. The first version of any organizational configuration rarely captures enough nuance to be genuinely useful expect to revise it.

Governance and Policy Development

Before deployment goes broad, a written policy is necessary at minimum covering what information should not be entered, how outputs get reviewed before use in client-facing or regulated contexts, how custom GPT configurations are approved, and who owns ongoing administration. This is not compliance overhead for its own sake. It is the operational foundation that separates deployments that create value from ones that create liability.

User Training and Change Management

The gap between a technically clean deployment and one that actually changes how people work is almost always a change management gap. Organizations that explain not just how the tool works but how it fits into the specific workflows employees care about see meaningfully higher adoption. Generic training — here is the tool, here is how to type into it produces generic usage. The early adopters pick it up; the rest carry on as before; the organization ends up with a subscription that serves a fraction of the people who could benefit from it.

Ongoing Evaluation

The technology moves quickly enough that a deployment decision made today will need revisiting. Capabilities that do not exist right now may be standard in six months. Pricing structures change. The competitive landscape shifts. Building in a lightweight review usage data quarterly, structured user feedback at regular intervals, a proper competitive revisit annually is more useful than treating the initial deployment decision as a settled conclusion.

Process Flows and Visual Reference

Document Analysis Workflow

The table below maps a structured process flow for document analysis use cases — reviewing a vendor contract or synthesizing a lengthy regulatory filing, for example. It is formatted as a sequential table that can be recreated as a flowchart in PowerPoint or Lucidchart.

Step	Action	Responsible Party	Output	Governance Checkpoint
1	Identify document and analysis objective	Business team	Defined scope and questions to answer	Confirm document is approved for submission per data policy
2	Upload document to ChatGPT Enterprise session	Business team or analyst	Document loaded into context	Verify no confidential third-party data present
3	Submit structured prompt with specific analysis questions	Analyst	Initial response from model	None at this stage
4	Review and interrogate output; follow-up as needed	Analyst	Refined analysis	Note any factual claims requiring independent verification
5	Verify key claims against source document or authoritative external source	Analyst or SME	Verified or corrected output	Required before use in any client-facing or regulated context
6	Integrate findings into work product	Business team	Final deliverable	Standard review and approval process applies

Enterprise Evaluation Decision Flow

The table below models the decision logic a procurement team would work through when evaluating whether ChatGPT Enterprise fits a given use case. Each row is a decision point with two paths forward.

Decision Point	Yes Path	No Path
Is the primary use case general knowledge work (writing, analysis, research)?	Continue evaluation	Assess purpose-built alternatives first
Can standard enterprise cloud security controls satisfy compliance requirements?	Continue evaluation	Engage legal/compliance before proceeding; may require dedicated deployment
Does the organization have technical resources to configure and maintain integrations?	Include custom GPT and API integration in scope	Scope to standard interface use cases only
Is the organization standardized on Microsoft 365 with E3/E5 licensing?	Evaluate Microsoft 365 Copilot in parallel	ChatGPT Enterprise likely has a simpler integration story
Is a domain-specific use case (legal, clinical, deep finance) the primary driver?	Evaluate purpose-built vertical tools alongside ChatGPT Enterprise	Proceed with ChatGPT Enterprise evaluation
Can the organization commit to governance and training investment?	Proceed to pilot	Delay deployment until governance framework is in place

Data for Custom Visualization: Feature Comparison by Vendor

The table below provides the underlying data for a radar chart comparing ChatGPT Enterprise, Microsoft 365 Copilot, and Google Duet AI across key evaluation dimensions. Scores are qualitative assessments on a 1–5 scale intended for visualization; treat them as directional, not independently verified.

Dimension	ChatGPT Enterprise	Microsoft 365 Copilot	Google Duet AI
General knowledge work quality	5	4	4
Native ecosystem integration	3	5	5
Security and compliance controls	4	5	4
Context window length	5	4	4
Custom configuration flexibility	4	3	3
Pricing transparency	2	4	4
Brand familiarity / adoption ease	5	5	4
Technical integration depth	3	5	4

Recreate this as a radar chart in Excel or PowerPoint using the scores above. The resulting visualization surfaces the trade-off clearly: ChatGPT Enterprise leads on raw capability and brand adoption; Microsoft and Google lead on ecosystem integration and pricing clarity.

Frequently Asked Questions

1. Does OpenAI use our data to train its models if we use ChatGPT Enterprise?

No. OpenAI's enterprise terms explicitly state that data submitted through ChatGPT Enterprise is not used for model training by default. This is a contractual commitment and represents a meaningful distinction from the consumer product. Organizations with specific requirements should review the Data Processing Agreement directly, as individual contract terms may vary.

2. What is the difference between ChatGPT Enterprise and ChatGPT Team?

ChatGPT Team is a scaled-up version of the consumer product with some administrative features and a data-no-training commitment. ChatGPT Enterprise provides a larger context window, more extensive admin controls, SSO support, audit logs, and dedicated account support. It is designed for larger organizational deployments with more complex governance

requirements. ChatGPT Team is the more appropriate choice for smaller organizations or teams that do not require enterprise-grade administrative infrastructure.

3. How is ChatGPT Enterprise priced?

OpenAI does not publish public pricing for ChatGPT Enterprise. Pricing is negotiated directly through the sales team and is structured as an annual contract with per-seat pricing that varies with volume. Organizations should request a detailed quote early in the evaluation process, as pricing can be a significant variable in the business case. Third-party reporting has suggested pricing in the range of \$30–\$60 per user per month depending on volume and contract terms, but these figures should not be treated as authoritative.

4. Can ChatGPT Enterprise access our internal documents and systems?

Not by default. Standard sessions allow users to upload documents manually within a session. To connect the tool to internal knowledge bases, CRM systems, or other organizational data sources, organizations need to configure custom GPT Actions, which require API integrations built and maintained by technical staff. This is a meaningful implementation effort, not a configuration toggle.

5. What is a custom GPT and why does it matter in an enterprise context?

A custom GPT is a pre-configured version of the model built around specific instructions, behavioral guidelines, and in some cases external data connections. In an enterprise context, custom GPTs allow organizations to deploy standardized tools for specific workflows — an HR policy assistant, a procurement process guide, a code documentation generator — without requiring every employee to craft effective prompts from scratch. The quality of the configuration determines the quality of the tool, and configurations require maintenance as organizational processes evolve.

6. Is ChatGPT Enterprise compliant with GDPR?

OpenAI has published documentation addressing GDPR compliance and offers a Data Processing Agreement for enterprise customers. Whether ChatGPT Enterprise satisfies a specific organization's GDPR obligations depends on the nature of the data being processed, the organization's role as data controller, and the specific regulatory interpretation applicable to its jurisdiction and industry. Legal and compliance review of the DPA and service agreement is recommended before deployment in the EU.

7. How does the context window size affect what we can do with the product?

The 128,000-token context window allows users to submit very large documents — most standard business documents, contracts, and reports fall within this limit — and receive analysis that accounts for the full content. In practical terms, it makes document-level analysis feasible without chunking documents into pieces. Performance is not perfectly uniform across very long contexts, however, and organizations should test representative documents before drawing conclusions about capability for their specific use cases.

8. What happens when the model produces a factually incorrect response?

The model may produce incorrect information with apparent confidence. There is no automated error-flagging mechanism that reliably identifies when the model has made a factual error. This is a fundamental characteristic of the technology, not a product defect that will be patched. The practical response is organizational: establish clear processes for reviewing outputs before use in any consequential context, train employees to treat outputs as starting points rather than authoritative sources, and pay particular attention to specific factual claims, calculations, and citations.

9. Is ChatGPT Enterprise suitable for regulated industries such as healthcare or financial services?

It can be used in regulated industries, but suitability depends on the specific use case and applicable regulations. Financial services organizations using it for general productivity tasks drafting internal communications, synthesizing research face different compliance considerations than those attempting to use it in client-facing advisory or regulated reporting contexts. Healthcare organizations processing protected health information face HIPAA requirements that require specific contractual arrangements. In both cases, the path to compliant deployment runs through legal and compliance review, not the product's standard enterprise security posture alone.

10. How should we measure return on investment from a ChatGPT Enterprise deployment?

The most credible ROI frameworks tie measurement to specific time-saving estimates in defined workflows. Before deployment, identify three to five workflows that are high-frequency, time-intensive, and well-suited to the product's capabilities. Establish a baseline time estimate for each. After a defined pilot period, measure actual time spent with the tool in place. Supplementing this with qualitative feedback on output quality and adoption patterns produces a more complete picture than time savings alone. Productivity claims made without this kind of baseline measurement should be treated skeptically.

Glossary

Term	Definition
Agentic workflow	A configuration where the tool takes sequential actions across multiple steps autonomously rather than responding to a single prompt. Emerging in enterprise AI products.
Audit log	A record of system activity, in this context a log of user interactions within a ChatGPT Enterprise workspace accessible to administrators for compliance and incident review purposes.
Context window	The maximum amount of text a language model can hold in active memory during a single session. Measured in tokens; affects how much document content can be submitted and referenced in a single interaction.
Custom GPT	A pre-configured version of the model built around organizational-specific instructions, behavioral guidelines, and in some cases external data connections. Deployable across an organizational workspace.
Data Processing Agreement (DPA)	A contractual document specifying how a vendor processes personal data on behalf of a customer, including security measures, subprocessor relationships, and data subject rights.
Foundation model	A large-scale model trained on broad data and capable of being adapted to a wide range of tasks. GPT-4 is the foundation model underlying ChatGPT Enterprise.
Hallucination	The production by a language model of confident, fluent output that is factually incorrect or fabricated. Not a product-specific defect; a characteristic of the underlying technology type.
Lost in the middle	A documented pattern in which language models perform less accurately on information appearing in the middle of a very long context, relative to information near the beginning or end.
RAG (Retrieval-Augmented Generation)	An architecture in which a language model is connected to an external knowledge source, retrieving relevant documents before generating a response. Used to improve factual accuracy and reduce reliance on training data alone.
SAML (Security Assertion Markup Language)	An open standard for exchanging authentication and authorization data between identity providers and service providers. The basis for SSO integration in ChatGPT Enterprise.

SOC 2 Type II	A third-party audit report assessing an organization's security, availability, processing integrity, confidentiality, and privacy controls over a period of time. Relevant to enterprise procurement processes.
SSO (Single Sign-On)	An authentication scheme that allows users to log into multiple applications with a single set of credentials, typically managed through a central identity provider such as Okta or Azure AD.
Token	The basic unit of text processing in language models. Approximately 750 words equal 1,000 tokens in English text, though this varies with the complexity of the language.
GPT Actions	A framework within the custom GPT system that allows a configured assistant to make API calls to external services, enabling retrieval of live data or triggering actions in connected systems.
